### General Description

The SS275 Omnipolar Hall effect sensor IC is fabricated from mixed signal CMOS technology .It incorporates advanced chopper-stabilization techniques to provide accurate and stable magnetic switch points. The output transistor of the SS275 will be latched on ( $B_{OP}$ ) in the presence of a sufficiently strong South or North magnetic field facing the marked side of the package. The output will be latched off ( $B_{RP}$ ) in the absence of a magnetic field.

The chopper stabilized amplifier uses switched capacitor techniques to eliminate the amplifier offset voltage, which, in bipolar devices, is a major source of temperature sensitive drift. CMOS makes this advanced technique possible. The CMOS chip is also much smaller than a bipolar chip, allowing very sophisticated circuitry to be placed in less space. The small chip size also contributes to lower physical stress and less power consumption.

## ESD Precautions

Electronic semiconductor products are sensitive to Electro Static Discharge (ESD). Always observe Electro Static Discharge control procedures whenever handling semiconductor products.

### Installation Comments

Consider temperature coefficients of Hall IC and magnetics , as well as air gap and life time variations. Observe temperature limits during wave soldering. Typical IR solder-reflow profile:

- No Rapid Heating and Cooling.
- Recommended Preheating for max. 2minutes at 150°C
- Recommended Reflowing for max. 5seconds at 240°C

### Application Informatio

It is strongly recommended that an external bypass capacitor be connected (in close proximity to the Hall sensor) between the supply ( $V_{DD}$  Pin) and ground (GND Pin) of the device to reduce both external noise and noise generated by the chopper stabilization technique. As is shown in the following two figures, a  $0.1\mu\text{F}$  capacitor is typical.

For reverse voltage protection, it is recommended to connect a resistor or a diode in series with the  $V_{DD}$  pin. When using a resistor, three points are important:

- the resistor has to limit the reverse current to 50mA maximum ( $V_{CC} / R1 \leq 50\text{mA}$ )
- the resulting device supply voltage  $V_{DD}$  has to be higher than  $V_{DD}$  min ( $V_{DD} = V_{CC} - R1 * I_{DD}$ )
- the resistor has to withstand the power dissipated in reverse voltage condition ( $PD = V_{CC}^2 / R1$ )

When using a diode, a reverse current cannot flow and the voltage drop is almost constant ( $\approx 0.7\text{V}$ ).

Therefore, a  $100\Omega/0.25\text{W}$  resistor for 5V application and a diode for higher supply voltage are recommended.

When a weak power supply is used or when the device is intended to be used in noisy environment, it is recommended that the second figure is used.

The low-pass filter formed by  $R1$  and  $C1$  and the Zener diode  $Z1$  bypass the disturbances or voltage spikes occur-

ring on the device supply voltage  $V_{DD}$ . The diode  $D1$  provides additional reverse voltage protection. Both solutions provide the required reverse voltage protection.
